

# The effects of patient online self-diagnosing in the ‘smart-phone society’ on the healthcare professional-patient relationship and medical authority

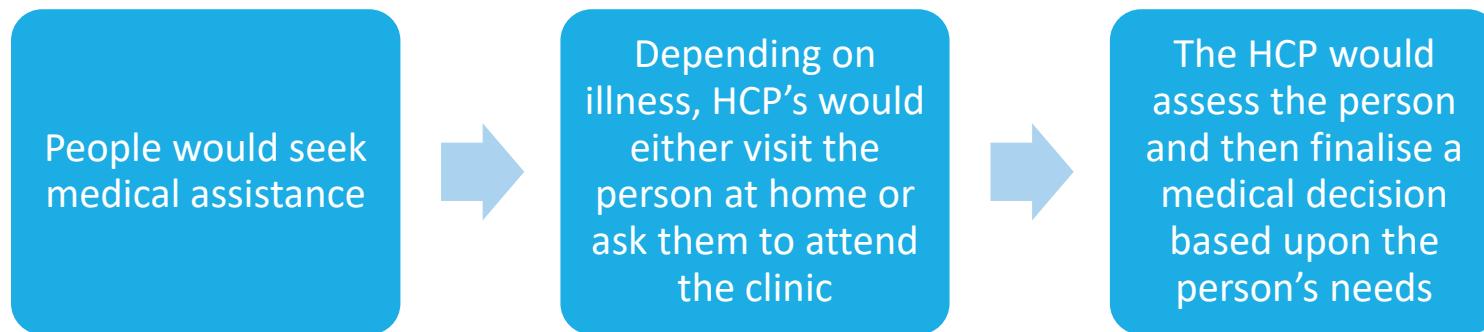

A mixed methods systematic review

Annabel Farnood  
PhD student  
The University of Glasgow

Supervisors: Professor Bridget Johnston & Professor Frances Mair

# Background

Traditionally, patient-healthcare professional relationships were encountered as below:

Kaba & Sooriakumaran (2007)

- The wealth of health information available online has now become influential in the patient-HCP relationship (Chrismann, 2013).
- The rising use of smartphones and rapidly increasing availability of health information on the internet has led to more people using the internet as their first healthcare resource, often before seeking professional advice (Gualtieri, 2009).

# Focus of the systematic review

---

Research questions:

1. What are the effects of patients seeking online health information on the healthcare professional-patient relationship and medical authority?
2. How do healthcare professionals perceive patients use of online health information?
3. How do public/patients perceive the use of online health information?

# Methods

---

## Search Strategy:

The systematic literature search was conducted using five databases: MEDLINE, EMBASE, CINAHL, ACM and SCOPUS. All searches were conducted using an 'advanced search' functionality, restricted to English language only and published between 2007 and 2018.

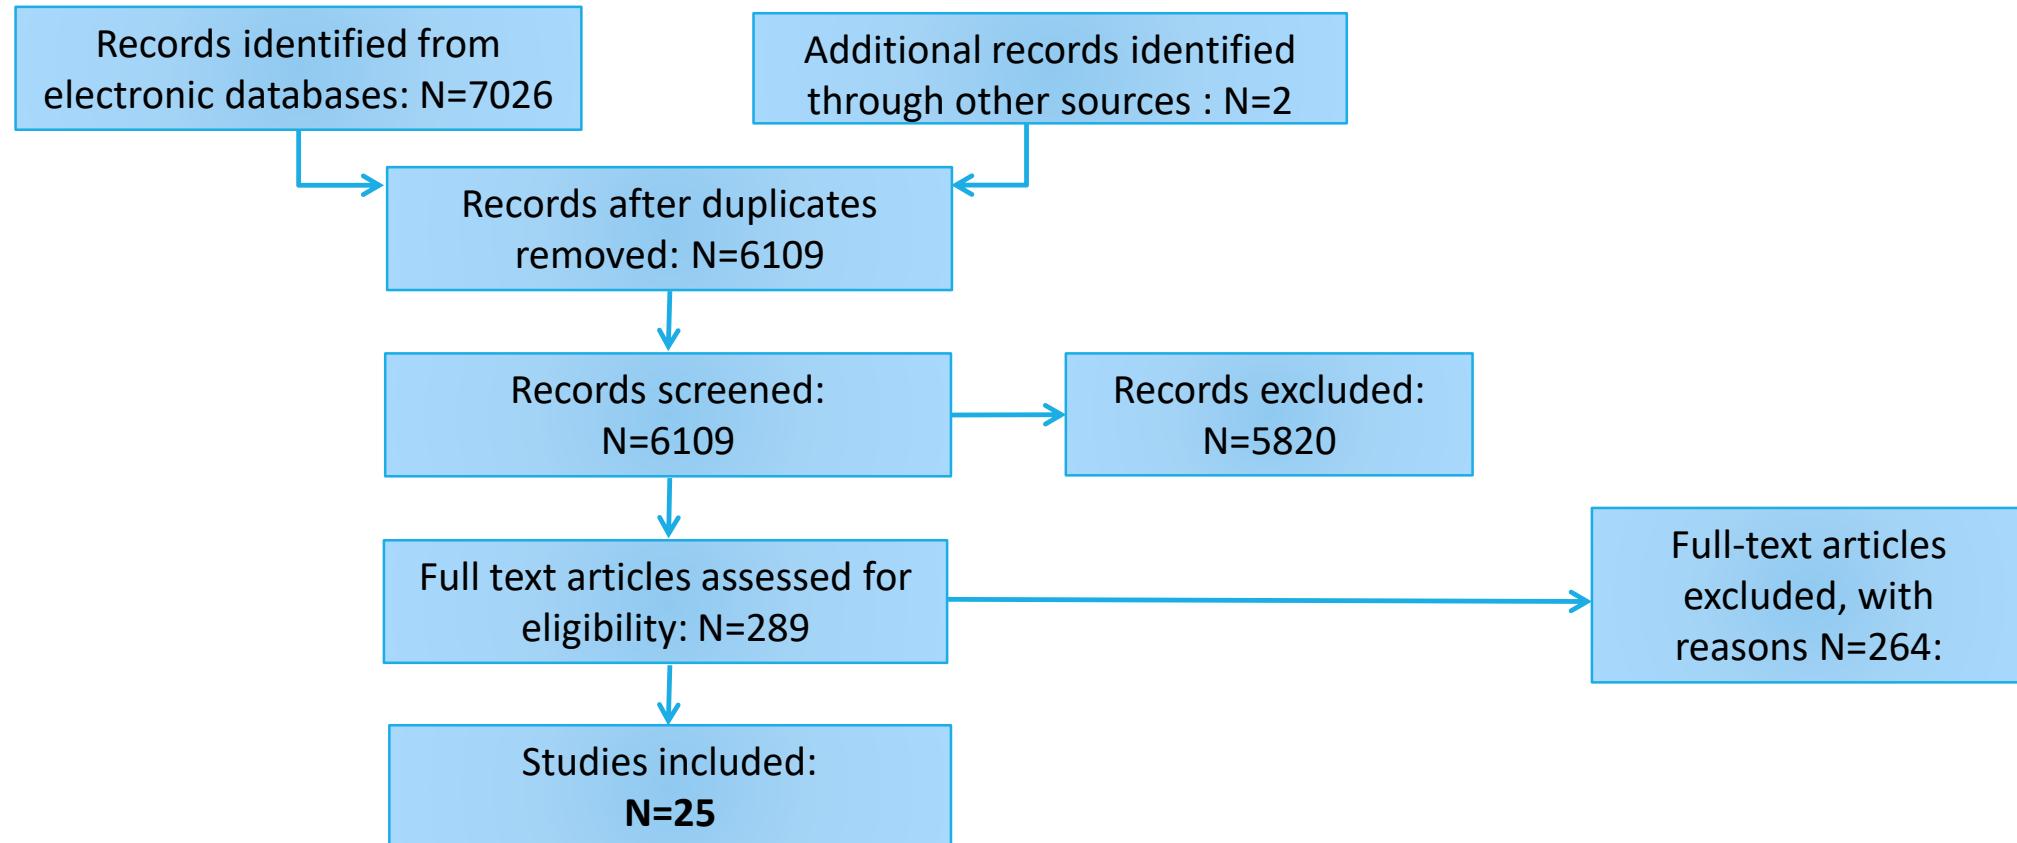

### Key terms:

'Digital health, smart phone, health information, self-diagnosis, patient, professional'

## Eligibility criteria:

- 2007 onwards
- Any individual (adult) over the age of 18. This includes patients, the public and health care professionals (including nurses).
- Any 'normal' primary care setting (community, primary care clinics, home, online, education facilities) qualified for inclusion. Hospital settings were excluded as they are known to be secondary care.
- Any physical health condition.
- Must be in relation to patient online self-diagnosing and information seeking on the internet.

# Results: Study Selection

# Results: Study characteristics

---

## Characteristics (25 studies)

Country	UK (5) USA (6) Israel (4) Switzerland (3) Australia (2) Canada (2) China (1) Portugal (1) Austria (1)
Design	Qualitative (16) Quantitative (8) Mixed Methods (1)
Setting	Primary care (12) Community (5) Online communities (5) Universities and educational departments (3)
Healthcare providers	GP's, Primary care nurses, Hospital nurses attending educational courses
Sample size	Range: 11-714
Quality appraisal (Mixed methods appraisal tool)	Low (4) Moderate (11) Moderate-High (4) High (4)

# Mapping themes to Normalisation Process Theory (NPT)

NPT is a useful framework to explain and understand how people integrate new interventions into their every day routines. It has four constructs: coherence; cognitive participation; collective action; and reflexive monitoring.

Collective action  
(enacting work)  
and reflexive  
monitoring  
(appraisal)

Sharing online  
health information  
with healthcare  
professionals

Patient/public  
perspectives on  
using the internet  
to seek health  
information

Coherence  
(sense making)  
and reflexive  
monitoring  
(appraisal)

Impact of online  
medical searches  
and diagnosis on  
patient-healthcare  
professional  
relationships

Healthcare  
professionals'  
perspectives on  
and reactions to  
internet-informed  
patients

Reflexive  
monitoring  
(appraisal)

Cognitive  
participations  
(relationship work);  
collective action  
(enacting work) and  
reflexive monitoring  
(appraisal work).

# Patient/public perspectives on using the internet to seek health information

---

- Studies reported that the first source patients accessed for health information was the internet.
- The internet was seen as a tool for the treatment of non-serious medical issues or for self-diagnosis.
- Countries that pay for healthcare services reported internet health seeking to be money saving and time efficient.
- 24/7 accessibility.
- Preparation for consultations.

# Patient/public perspectives on using the internet to seek health information

---

- There were reported concerns about the credibility, limitation and trustworthiness of online information.
- Overwhelming amount of information can result in masking credible sources.

# Healthcare professionals' perspectives on and reactions to internet-informed patients

- Taking responsibility for their own health and be able to make decisions.
- Importance of collaboration with patients.
- Lack of trust in their medical expertise.
- The internet poses risks as patients may misinterpret information and this can also cause unnecessary medical visits.
- Preventing HCP's to do their jobs effectively.

# Sharing online health information with healthcare professionals

## Reasons for:

- Investing time and energy into their health and preparing for the consultation.
- Enabling better communication with HCP's.
- Positive experiences: listening, acknowledging, body language and offering further discussion.

## Reasons against:

- Felt the sources online were unreliable.
- Not enough time to share in consultations.
- Some people felt they would be challenging the HCP and did not want to question or offend them.

# Impact of online medical searches and diagnosis on patient-healthcare professional relationships

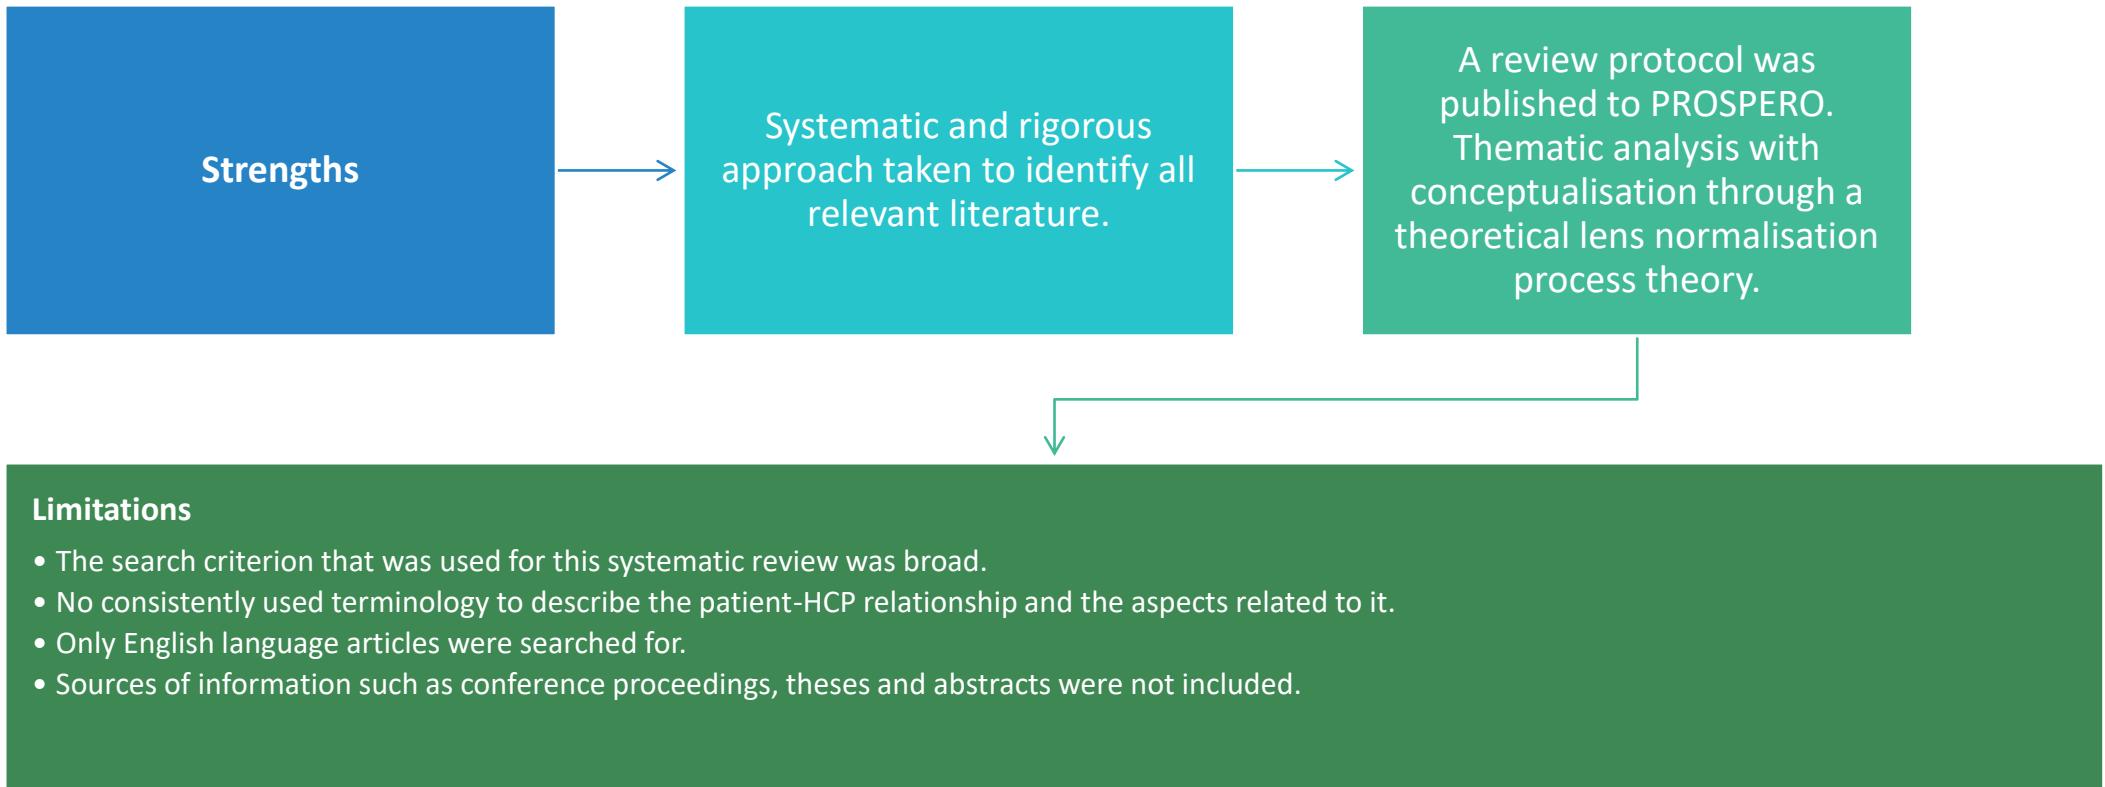

- Most people felt more trust in their HCP's but hoped for discussion regarding online health information.
- Some HCP's deliberately showed interest in patients research to promote further self-care.
- HCP's described their roles as changing into a 'partner to the patient'.
- Online medical searching may cause misunderstandings between the patient and HCP's.
- Studies reported patients tended to present information to the HCP to support the therapeutic relationship rather than to challenge it.

# Implications for nursing

# Strengths and weaknesses

## Discussion

A large proportion of people found health information obtained online to be a complementary information source, that was in addition to treatment information obtained from a HCP.

It was clear that patients felt they had a better relationship with their HCP when they were able to discuss their online research with them and when their HCP responded positively to this.

Online health information has the potential to positively improve the relationship.
